Conceptual schema

E2

Relation schemas

?

Introduction

- Each *relation schema* consists of a number of attributes and the *relational database schema* consists of a number of relation schemas.
- Attributes are grouped to form a relation schema.
- Need some formal measure of why one grouping of attributes into a relation schema may be better than another.

Introduction

- “Goodness” measures:
  - Redundant information in tuples.
  - Update anomalies: modification, deletion, insertion.
  - Reducing the NULL values in tuples.
  - Disallowing the possibility of generating spurious tuples.

Redundant information

- The attribute values pertaining to a particular department (DNUMBER, DNAME, DMGRSSN) are repeated for *every employee who works for that department*.

Redundancy

EMP_DEPT

Ename	Ssn	Bdate	Address	Dnumber	Dname	Dmgr_ssn
Smith, John B.	123456789	1965-01-09	731 Fondren, Houston, TX	5	Research	333445555

Zelaya, Alicia J.	999887777	1968-07-19	3321 Castle, Spring, TX	4	Administration	987654321
Wallace, Jennifer S.	987654321	1941-06-20	291 Berry, Bellaire, TX	4	Administration	987654321
Narayan, Ramesh K.	666884444	1962-09-15	975 FireOak, Humble, TX	5	Research	333445555
English, Joyce A.	453453453	1972-07-31	5631 Rice, Houston, TX	5	Research	333445555
Jabbar, Ahmad V.	987987987	1969-03-29	980 Dallas, Houston, TX	4	Administration	987654321
Borg, James E.	888665555	1937-11-10	450 Stone, Houston, TX	1	Headquarters	888665555

Update anomalies

- Update anomalies: modification, deletion, insertion
  - Modification
    - As the manager of a dept. changes we have to update many values according to employees working for that dept.
    - Easy to make the DB **inconsistent.**

EMP_DEPT

Ename	Ssn	Bdate	Address	Dnumber	Dname	Dmgr_ssn
Smith, John B.	123456789	1965-01-09	731 Fondren, Houston, TX	5	Research	333445555
Wong, Franklin T.	333445555	1955-12-08	638 Voss, Houston, TX	5	Research	333445555
Zelaya, Alicia J.	999887777	1968-07-19	3321 Castle, Spring, TX	4	Administration	987654321

English, Joyce A.	453453453	1972-07-31	5631 Rice, Houston, TX	5	Research	333445555
Jabbar, Ahmad V.	987987987	1969-03-29	980 Dallas, Houston, TX	4	Administration	987654321
Borg, James E.	888665555	1937-11-10	450 Stone, Houston, TX	1	Headquarters	888665555

Update anomalies

- Update anomalies: modification, deletion, insertion
  - Deletion: if Borg James E. leaves, we delete his tuple and lose the existing of dept. 1, the name of dept. 1, and who is the manager of dept. 1.

EMP_DEPT

Ename	Ssn	Bdate	Address	Dnumber	Dname	Dmgr_ssn

Jabbar, Ahmad V.	987987987	1969-03-29	980 Dallas, Houston, TX	4	Administration	987654321
Borg, James E.	888665555	1937-11-10	450 Stone, Houston, TX	1	Headquarters	888665555

Reducing NULL values

- Employees not assigned to any dept.: waste the storage space.
- Other difficulties: aggregation operations (e.g., COUNT, SUM) and joins.

Generation spurious tuples

- Disallowing the possibility of generating spurious tuples.

  EMP_PROJ(SSN, PNUMBER, HOURS, ENAME, PNAME, PLOCATION)

  EMP_LOCS(ENAME, PLOCATION)

  EMP_PROJ1(SSN, PNUMBER, HOURS, PNAME, PLOCATION)

- Generation of invalid and spurious data during JOINS: PLOCATION is the attribute that relates EMP_LOCS and EMP_PROJ1, and PLOCATION is neither a primary key nor a foreign key in either EMP_LOCS or EMP_PROJ1 .

Generation spurious tuples

(b)

Summary of Design Guidelines

- "Goodness" measures:
  - Redundant information in tuples
  - Update anomalies: modification, deletion, insertion
  - Reducing the NULL values in tuples
  - Disallowing the possibility of generating spurious tuples

  ☞ Normalization
- It helps DB designers determine the best relation schemas.
  - A formal framework for analyzing relation schemas based on their keys and on the functional dependencies among their attributes.
  - A series of normal form tests that can be carried out on individual relation schemas so that the relational database can be normalized to any desired degree.
- It is based on the concept of normal form 1NF, 2NF, 3NF, BCNF, 4NF, 5 NF.

Contents

Functional Dependencies (FDs)

- Definition of FD
- Direct, indirect, partial dependencies
- Inference Rules for FDs
- Equivalence of Sets of FDs
- Minimal Sets of FDs

Definition of Functional dependencies

- Functional dependencies (FDs) are used to specify *formal measures* of the "goodness" of relational designs.
- FDs and keys are used to define **normal forms** for relations.
- FDs are **constraints** that are derived from the *meaning* and *interrelationships* of the data attributes.
- A set of attributes X *functionally determines* a set of attributes Y if the value of X determines a unique value for Y.

Definition of Functional dependencies

- X -> Y holds if whenever two tuples have the same value for X, they *must have* the same value for Y
- For any two tuples t1 and t2 in any relation instance r(R): *If* t1[X]=t2[X], *then* t1[Y]=t2[Y]
- X -> Y in R specifies a *constraint* on all relation instances r(R)
- Examples:
  - social security number determines employee name:

    SSN -> ENAME
  - project number determines project name and location:

    PNUMBER -> {PNAME, PLOCATION}
  - employee ssn and project number determines the hours per week that the employee works on the project:

    {SSN, PNUMBER} -> HOURS

Definition of Functional dependencies

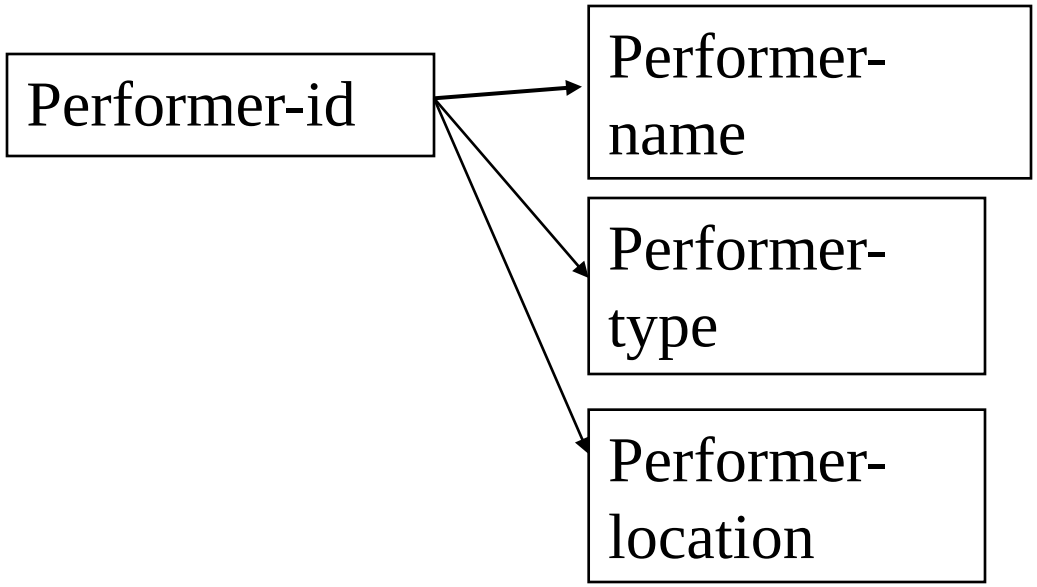
- If K is a key of R, then K functionally determines all attributes in R (since we never have two distinct tuples with t1[K]=t2[K]).

Functional Dependencies (FDs)

- Definition of FD
- Direct, indirect, partial dependencies
- Inference Rules for FDs
- Equivalence of Sets of FDs
- Minimal Sets of FDs

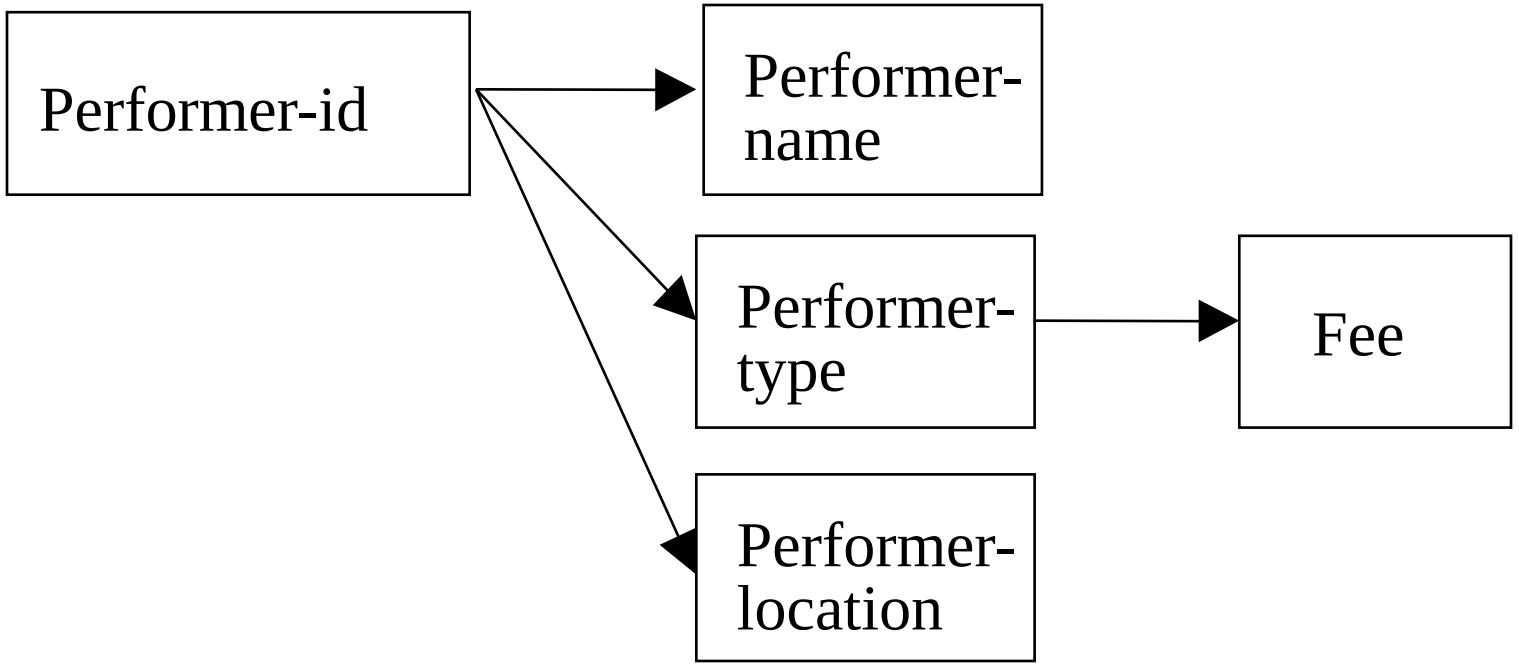
Direct, indirect, partial dependencies

- **Direct dependency (fully functional dependency):** All attributes in a R must be fully functionally dependent on the primary key (or the PK is a determinant of all attributes in R).



Direct, indirect, partial dependencies

- **Indirect dependency (transitive dependency):** Value of an attribute is not determined directly by the primary key.



Direct, indirect, partial dependencies

- Partial dependency
  - **Composite determinant**: more than one value is required to determine the value of another attribute, the combination of values is called a composite determinant.

EMP_PROJ(SSN, PNUMBER, HOURS, ENAME, PNAME, PLOCATION)

{SSN, PNUMBER} -> HOURS

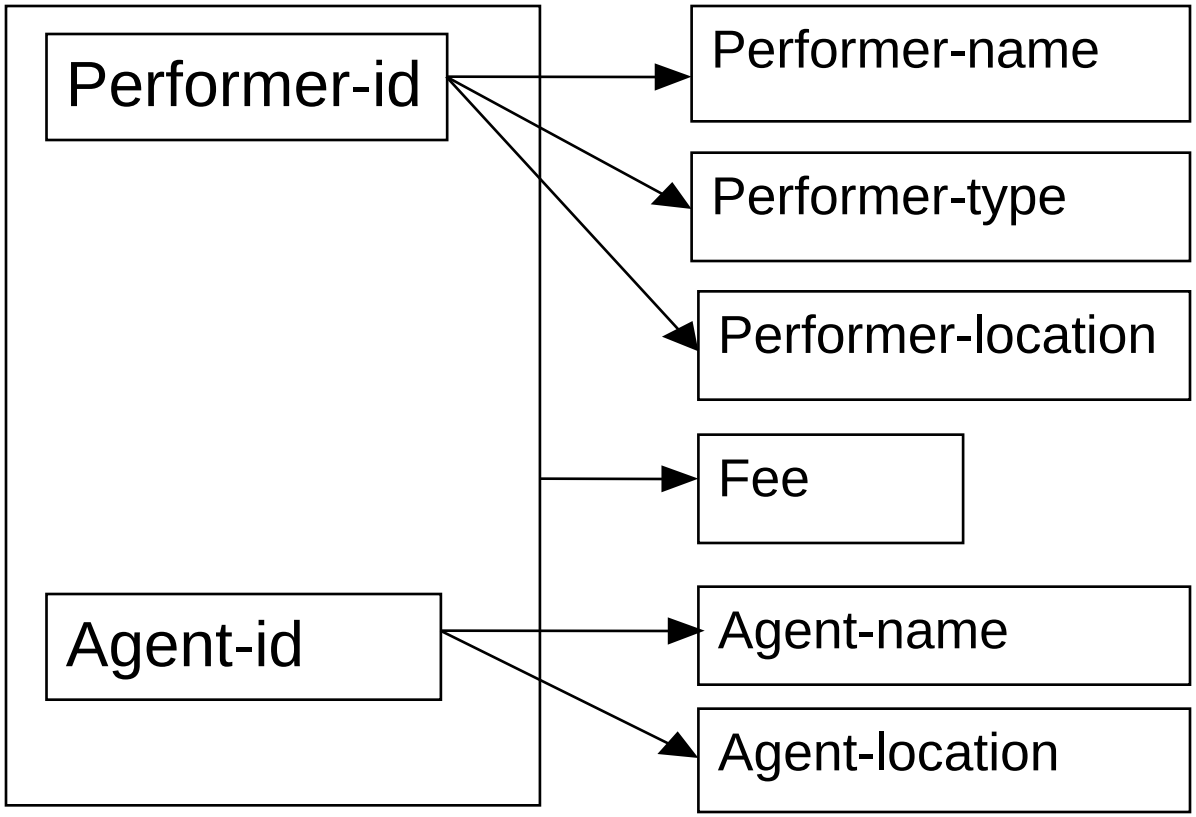
  - **Partial dependency**: if the value of an attribute does not depend on an entire composite determinant, but only part of it, the relationship is known as the partial dependency.

SSN -> ENAME

PNUMBER -> {PNAME, PLOCATION}

Direct, indirect, partial dependencies

- Partial dependency



Functional Dependencies (FDs)

- Definition of FD
- Direct, indirect, partial dependencies
- Inference Rules for FDs
- Equivalence of Sets of FDs
- Minimal Sets of FDs

Inference Rules for FDs

- Given a set of FDs F, we can *infer* additional FDs that hold whenever the FDs in F hold.

Armstrong's inference rules:

IR1. (**Reflexive**) If $Y \subseteq X$, then X -> Y.

IR2. (**Augmentation**) If X -> Y, then XZ -> YZ.

(Notation: XZ stands for X U Z)

IR3. (**Transitive**) If X -> Y and Y -> Z, then X -> Z.

Inference Rules for FDs

- Some **additional inference rules** that are useful:

  (**Decomposition**) If X -> YZ, then X -> Y and X -> Z

  (**Union**) If X -> Y and X -> Z, then X -> YZ

  (**Psuedotransitivity**) If X -> Y and WY -> Z, then WX -> Z

- The last three inference rules, as well as any other inference rules, can be deduced from IR1, IR2, and IR3 (completeness property).

Inference Rules for FDs

- **Closure** of a set F of FDs is the set F^+ of all FDs that can be inferred from F.
- **Closure** of a set of attributes X with respect to F is the set X^+ of all attributes that are functionally determined by X.
- X^+ can be calculated by repeatedly applying IR1, IR2, IR3 using the FDs in F.

Inference Rules for FDs

Algorithm 16.1. Determining X^+, the Closure of X under F

Input: A set F of FDs on a relation schema R, and a set of attributes X, which is a subset of R.

$X^+ := X$;
repeat
    old$X^+ := X^+$;
    for each functional dependency $Y \rightarrow Z$ in F do
        if $X^+ \supseteq Y$ then $X^+ := X^+ \cup Z$;
until (X^+ = oldX^+);

Inference Rules for FDs

- Consider a relation *R*(*A*, *B*, *C*, *D*, *E*) with the following dependencies F:
- *(1) AB → C,*
- *(2) CD → E,*
- *(3) DE → B*
- **Find {A,B}$^+$?**

Functional Dependencies (FDs)

- Definition of FD
- Direct, indirect, partial dependencies
- Inference Rules for FDs
- Equivalence of Sets of FDs
- Minimal Sets of FDs

Equivalence of Sets of FDs

- Two sets of FDs F and G are **equivalent** if $F^+ = G^+$.
- Definition: F **covers** G if $G^+ \subseteq F^+$. F and G are equivalent if F covers G and G covers F.
- There is an algorithm for checking equivalence of sets of FDs.

Functional Dependencies (FDs)

- Definition of FD
- Direct, indirect, partial dependencies
- Inference Rules for FDs
- Equivalence of Sets of FDs
- Minimal Sets of FDs

Minimal Sets of FDs

- A set of FDs is **minimal** if it satisfies the following conditions:
  (1) Every dependency in F has a single attribute for its right-hand side.
  (2) We cannot remove any dependency from F and have a set of dependencies that is equivalent to F.
  (3) We cannot replace any dependency X -> A in F with a dependency Y -> A, where Y proper-subset-of X (Y subset-of X) and still have a set of dependencies that is equivalent to F.

Minimal Sets of FDs

Algorithm 16.2. Finding a Minimal Cover *F* for a Set of Functional Dependencies *E*

Input: A set of functional dependencies E.

1. Set *F* := *E*.

2. Replace each functional dependency $X \rightarrow \{A1, A2, ..., An\}$ in *F* by the *n* functional dependencies $X \rightarrow A1$, $X \rightarrow A2$, ..., $X \rightarrow An$.

3. For each functional dependency $X \rightarrow A$ in *F*

for each attribute *B* that is an element of *X*

if $\{ \{F - \{X \rightarrow A\} \} \cup \{ (X - \{B\}) \rightarrow A\} \}$ is equivalent to *F*

then replace $X \rightarrow A$ with $(X - \{B\}) \rightarrow A$ in *F*.

4. For each remaining functional dependency $X \rightarrow A$ in *F*

if $\{F - \{X \rightarrow A\} \}$ is equivalent to *F*,

then remove $X \rightarrow A$ from *F*.

Minimal Sets of FDs

- Every set of FDs has an equivalent minimal set.
- There can be several equivalent minimal sets.
- There is no simple algorithm for computing a minimal set of FDs that is equivalent to a set F of FDs.
- To synthesize a set of relations, we assume that we start with a set of dependencies that is a minimal set.

Contents

Normalization

- **Normalization**: The process of decomposing unsatisfactory "bad" relations by breaking up their attributes into smaller relations.
- **Normal form**: Using keys and FDs of a relation to certify whether a relation schema is in a particular normal form.
- **Normalization** is carried out in practice so that the resulting designs are of high quality and meet the desirable properties.
- The database designers ***need not*** normalize to the highest possible normal form (3NF, BCNF or 4NF).

Normalization

- There are two important properties of decompositions:
  (a) non-additive or losslessness of the corresponding join.
  (b) preservation of the functional dependencies.

- Note that property (a) is extremely important and *cannot* be sacrificed. Property (b) is less stringent and may be sacrificed (see chapter 16).

Normalization

- **Superkey** of R: A set of attributes **SK** of **R** such that no two tuples in any valid relation instance r(R) will have the same value for SK. That is, for any distinct tuples t1 and t2 in r(R), t1[SK] ≠ t2[SK].
- **Key** of R: A **"minimal" superkey**; that is, a superkey K such that removal of any attribute from K results in a set of attributes that is not a superkey.
- If K is a **key** of R, then K **functionally determines all attributes** in R.

Normalization

- Two new concepts:
  - A **Prime attribute** must be a member of *some candidate key.*
  - A **Nonprime attribute** is not a prime attribute: it is not a member of any candidate key.

Normalization

- 1NF and dependency problems
- 2NF – solves partial dependency
- 3NF – solves indirect dependency
- BCNF – well-normalized relations

1NF

- First normal form (1NF): there is only one value at the intersection of each row and column of a relation - no set valued attributes in 1 NF → Disallows composite attributes, multivalued attributes, and **nested relations.**

- The only attribute values permitted by 1NF are single **atomic** (or **indivisible**) **values**.

Normalization

- 1NF and dependency problems
- 2NF – solves partial dependency
- 3NF – solves indirect dependency
- BCNF – well-normalized relations

2NF

- Second normal form (2NF) - all attributes must be fully functionally dependent on the primary key.
- 2NF solves partial dependency problem in 1NF.
- **2NF normalized:** Decompose and set up a new relation for each partial key with its dependent attribute(s).Make sure to keep a relation with the original primary key and any attributes that are fully functionally dependent on it.

- Problem with 2NF:
  - Insertion
  - Modification
  - Deletion

Normalization

- 1NF and dependency problems
- 2NF – solves partial dependency
- 3NF – solves indirect dependency
- BCNF – well-normalized relations

3NF

- A relation schema R is in **third normal form** (**3NF**) if it is in 2NF *and* no non-prime attribute A in R is transitively dependent on the primary key.

- **NOTE:**
  - In X -> Y and Y -> Z, with X as the primary key, we consider this a problem only if Y is not a candidate key. When Y is a candidate key, there is no problem with the transitive dependency .
  - E.g., Consider EMP (SSN, Emp#, Salary).
  - Here, SSN → Emp#. Emp# → Salary and Emp# is a candidate key.

3NF

- 3NF solves indirect (transitive) dependencies problem in 1NF and 2NF.

- **3NF normalized:** identify all transitive dependencies and each transitive dependency will form a new relation.

SUMMARY OF NORMAL FORMS based on Primary Keys

Summary of Normal Forms Based on Primary Keys and Corresponding Normalization

Normal Form	Test	Remedy (Normalization)
First (1NF)	Relation should have no multivalued attributes or nested relations.	Form new relations for each multivalued attribute or nested relation.
Second (2NF)	For relations where primary key contains multiple attributes, no nonkey attribute should be functionally dependent on a part of the primary key.	Decompose and set up a new relation for each partial key with its dependent attribute(s). Make sure to keep a relation with the original primary key and any attributes that are fully functionally dependent on it.
Third (3NF)	Relation should not have a nonkey attribute functionally determined by another nonkey attribute (or by a set of nonkey attributes). That is, there should be no transitive dependency of a nonkey attribute on the primary key.	Decompose and set up a relation that includes the nonkey attribute(s) that functionally determine(s) other nonkey attribute(s).

General Normal Form Definitions

- The above definitions consider the primary key only.
- The following more general definitions take into account relations with multiple candidate keys.

General Normal Form Definitions

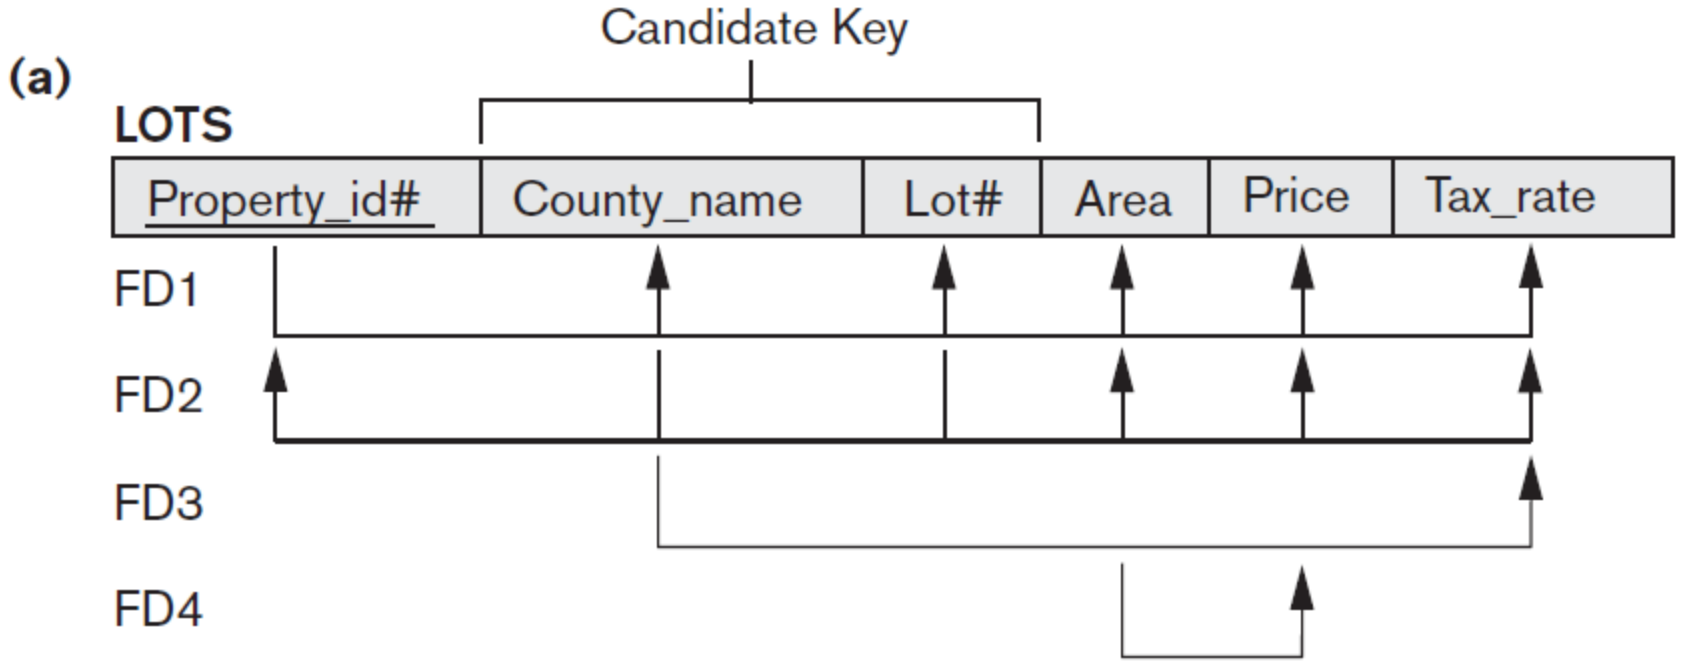
- A relation schema R is in **second normal form** (**2NF**) if every non-prime attribute A in R is *not partially functionally dependent* on *any key* of R.

- A relation schema R is in **third normal form** (**3NF**) if whenever a FD X → A holds in R, then either:

  (a) X is a superkey of R, or

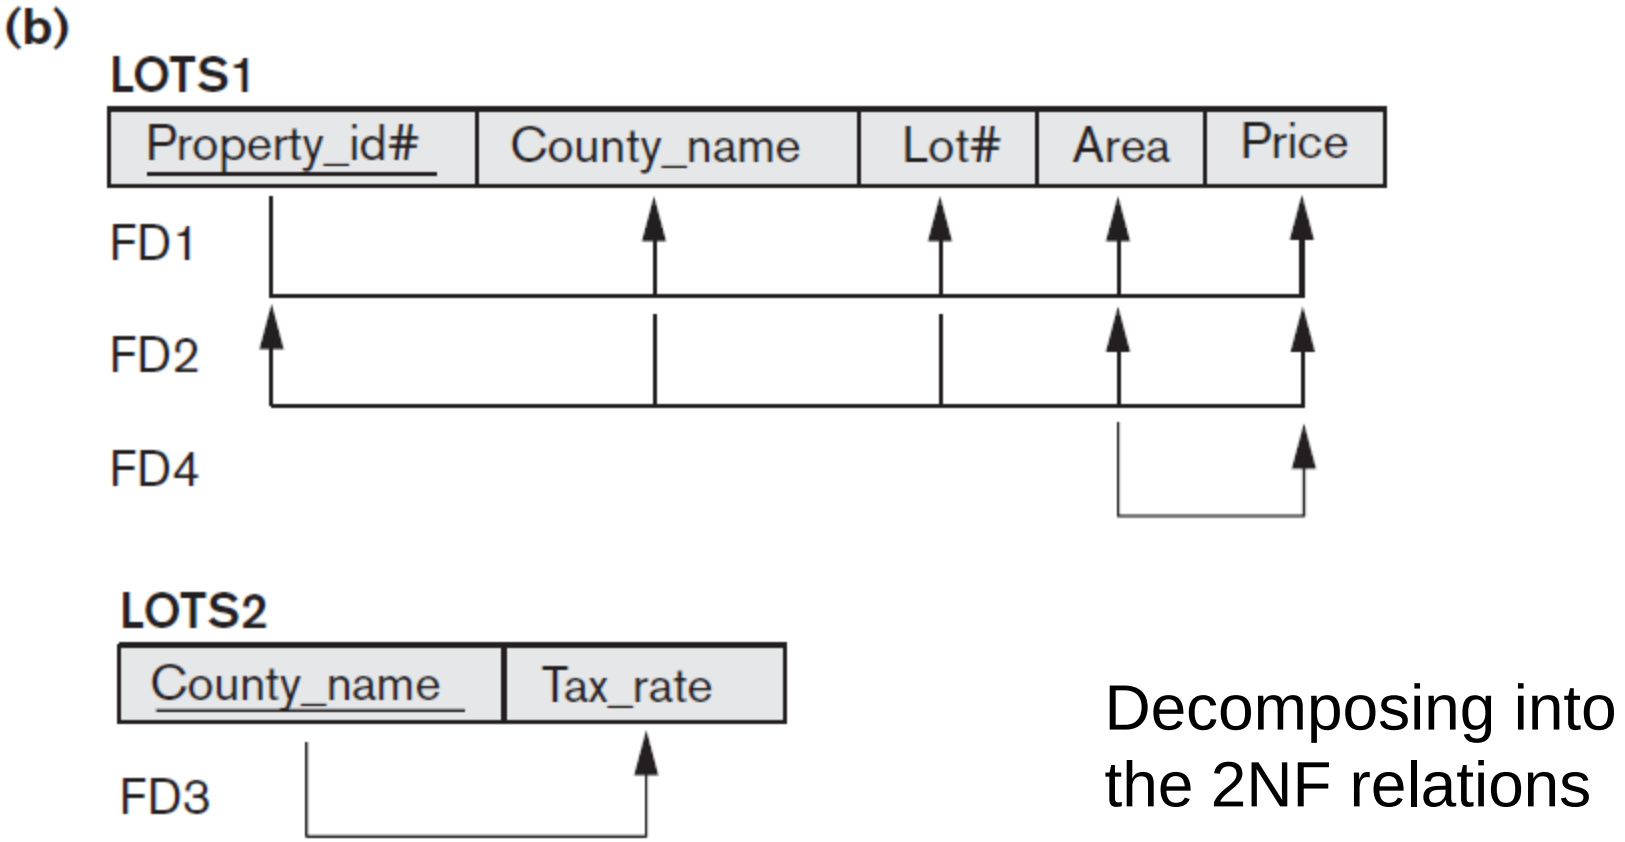
  (b) A is a prime attribute of R

General Normal Form Example



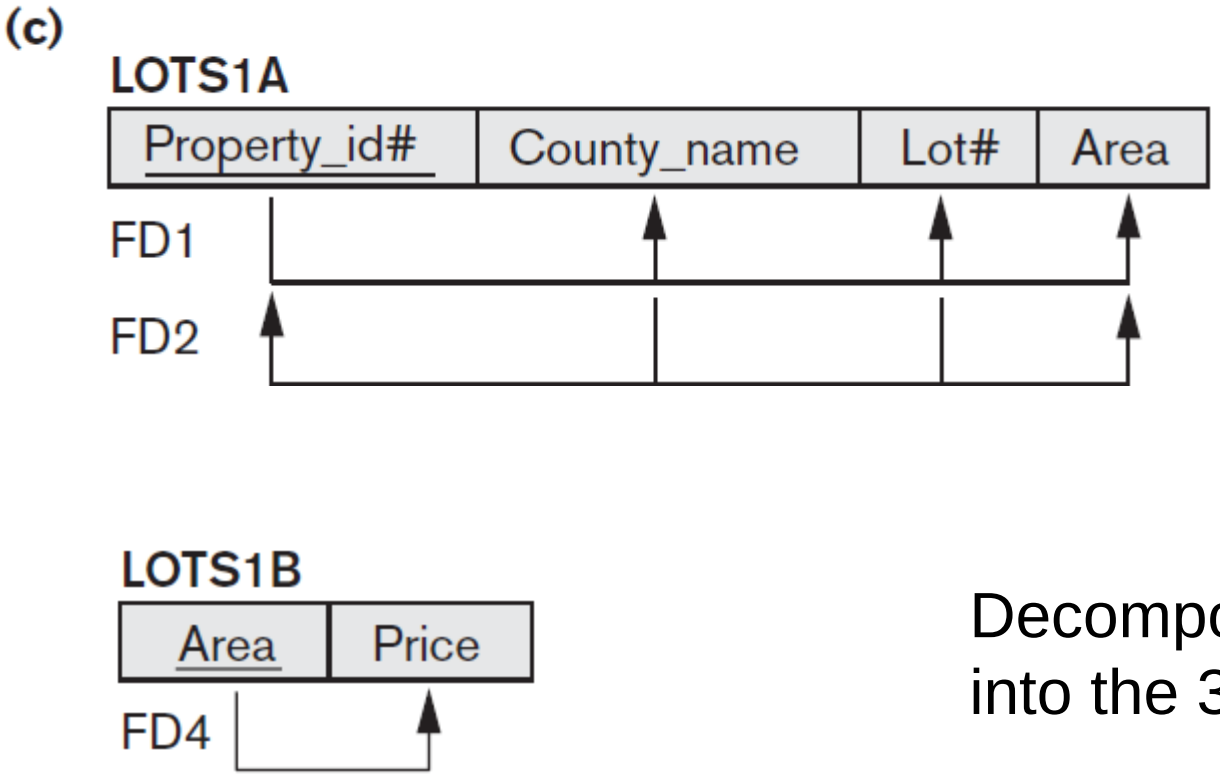
The LOTS relation with its functional dependencies.

General Normal Form Example



Decomposing into the 2NF relations

General Normal Form Example



Decomposing LOTS1 into the 3NF relations

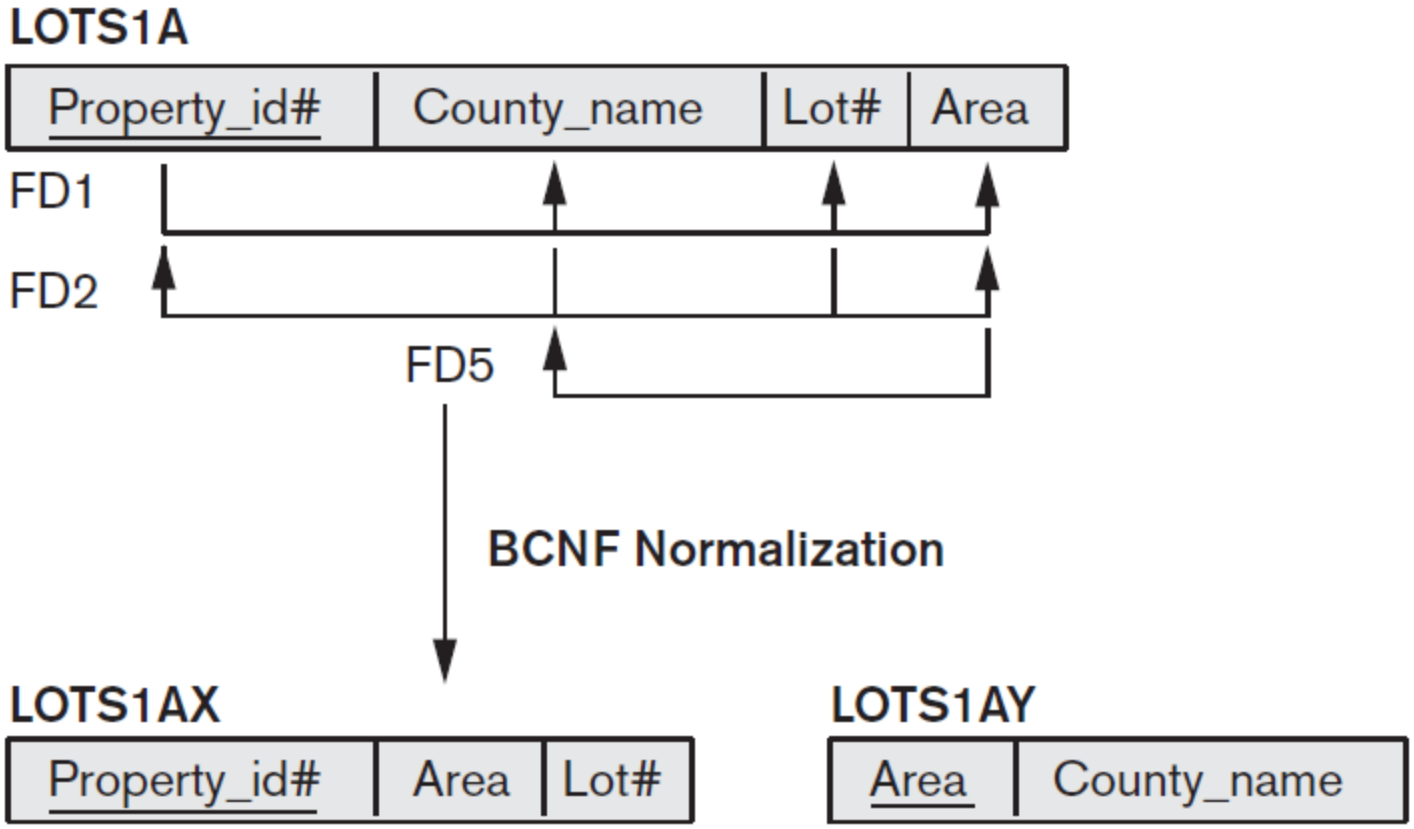
Normalization

- 1NF and dependency problems
- 2NF – solves partial dependency
- 3NF – solves indirect dependency
- BCNF – well-normalized relations

BCNF

- A relation schema R is in **Boyce-Codd Normal Form** (**BCNF**) if whenever an FD X -> A holds in R, then X is a superkey of R.

BCNF



BCNF normalization of LOTS1A with the functional dependency FD2 being lost in the decomposition.

BCNF

- TEACH (Student, Course, Instructor)
- FD1: {Student, Course} → Instructor
- FD2: Instructor → Course

TEACH

Student	Course	Instructor
Narayan	Database	Mark
Smith	Database	Navathe
Smith	Operating Systems	Ammar
Smith	Theory	Schulman
Wallace	Database	Mark
Wallace	Operating Systems	Ahamad
Wong	Database	Omiecinski
Zelaya	Database	Navathe
Narayan	Operating Systems	Ammar

BCNF

- Three possible pairs:
  1. {Student, Instructor} and {Student, Course}
  2. {Course, Instructor} and {Course, Student}
  3. {Instructor, Course} and {Instructor, Student}

- All three decompositions *lose the functional dependency FD1*. The desirable decomposition of those just shown is 3 because it will not generate spurious tuples after a join.

Notes & Suggestions

- [1], chapter 15:
  - 4NF: based on *multivalued dependency* (MVD)
  - 5NF: based on join dependency
    - Such a dependency is very difficult to detect in practice and therefore, normalization into 5NF is considered very rarely in practice
  - Other normal forms & algorithms
  - ER modeling: top-down database design
    - Bottom-up database design ??
- [1], chapter 16: Properties of Relational Decompositions

Contents

Dependency-Preserving Decomposition into 3NF Schemas

Algorithm 16.4. Relational Synthesis into 3NF with Dependency Preservation

Input: A universal relation *R* and a set of functional dependencies *F* on the attributes of *R*.

1. Find a minimal cover *G* for *F* (use Algorithm 16.2);

2. For each left-hand-side *X* of a functional dependency that appears in *G*, create a relation schema in *D* with attributes {*X* ∪ {A_1} ∪ {A_2} ... ∪ {A_k} }, where $X \rightarrow A_1$, $X \rightarrow A_2$, ..., $X \rightarrow A_k$ are the only dependencies in *G* with *X* as the left-hand-side (*X* is the key of this relation);

3. Place any remaining attributes (that have not been placed in any relation) in a single relation schema to ensure the attribute preservation property.

Nonadditive Join Decomposition into BCNF Schemas

Algorithm 16.5. Relational Decomposition into BCNF with Nonadditive Join Property

Input: A universal relation *R* and a set of functional dependencies *F* on the attributes of *R*.

1. Set *D* := {*R*} ;

2. While there is a relation schema *Q* in *D* that is not in BCNF do

{

choose a relation schema *Q* in *D* that is not in BCNF;

find a functional dependency $X \rightarrow Y$ in *Q* that violates BCNF;

replace *Q* in *D* by two relation schemas (*Q* – *Y*) and ($X \cup Y$);

} ;

Dependency-Preserving and Nonadditive (Lossless) Join Decomposition into 3NF Schemas

Algorithm 16.6. Relational Synthesis into 3NF with Dependency Preservation and Nonadditive Join Property

Input: A universal relation *R* and a set of functional dependencies *F* on the attributes of *R*.

1. Find a minimal cover *G* for *F* (use Algorithm 16.2).

2. For each left-hand-side *X* of a functional dependency that appears in *G*, create a relation schema in *D* with attributes $\{X \cup \{A_1\} \cup \{A_2\} \ldots \cup \{A_k\}\}$, where $X \rightarrow A_1$, $X \rightarrow A_2$, ..., $X \rightarrow A_k$ are the only dependencies in *G* with *X* as left-hand-side (*X* is the key of this relation).

3. If none of the relation schemas in *D* contains a key of *R*, then create one more relation schema in *D* that contains attributes that form a key of *R*.

4. Eliminate redundant relations from the resulting set of relations in the relational database schema. A relation *R* is considered redundant if *R* is a projection of another relation *S* in the schema; alternately, *R* is subsumed by *S*

Dependency-Preserving and Nonadditive (Lossless) Join Decomposition into 3NF Schemas

- Algorithm 16.6:
  - Preserves dependencies.
  - Has the nonadditive join property.
  - Is such that each resulting relation schema in the decomposition is in 3NF.

- It is preferred over Algorithm 16.4.

Key-finding algorithm (1)

By Elmasri and Navathe

Algorithm 16.2(a). Finding a Key *K* for *R* Given a set *F* of Functional Dependencies

Input: A relation *R* and a set of functional dependencies *F* on the attributes of *R*.

1. Set *K* := *R*.

2. For each attribute *A* in *K*

{compute $(K – A)^+$ with respect to *F*;

if $(K – A)^+$ contains all the attributes in R,

then set K := K – {A}

};

Key-finding algorithm (1)

By Elmasri and Navathe

- In algorithm (1), we start by setting K to all the attributes of R; we then remove one attribute at a time and check whether the remaining attributes still form a superkey.
- The algorithm (1) determines only **one key** out of the possible candidate keys for R; the key returned depends on the order in which attributes are removed from R in step 2.

Key-finding algorithm (2)

By Hossein Saiedian and Thomas Spencer

Input: A relation R and a set of functional dependencies F on the attributes of R.

Output: all candidate keys of R

Let:

- ***U*** contain **all** attributes of R.
- U_L contain attributes of R that occur **only** on the **left-hand side** of FDs in F.
- U_R contain attributes of R that occur **only** on the **right-hand side** of FDs in F.
- U_B contain attributes of R that occur on **both sides** of FDs in F.

Key-finding algorithm (2)

By Hossein Saiedian and Thomas Spencer

Note:

- $U_L \cap U_R = \phi$, $U_L \cap U_B = \phi$ and $U_R \cap U_B = \phi$
- $U_L \cup U_R \cup U_B = U$
- For every attribute $A \in U$, if $A \in U_L$, then A **must be** part of every candidate key of **R**.
- For every attribute $A \in U$, if $A \in U_R$, then A will **not** be part of any candidate key of **R.**

Key-finding algorithm (2)

By Hossein Saiedian and Thomas Spencer

Input: *A relation R and a set of functional dependencies F on the attributes of R.*

Output: *all candidate keys of R*

1. Determine $\boldsymbol{U_L}$, $\boldsymbol{U_R}$ and $\boldsymbol{U_B}$
2. If $\boldsymbol{U_L}^{+}_{\ddagger} = \boldsymbol{U}$ under F, then $\boldsymbol{U_L}$ forms the only key of R and the algorithm stops here.

   Else: move to step 3 // $\boldsymbol{U_L}^{+} \neq \boldsymbol{U}$ under F
3. Consider every subsets $\boldsymbol{U_{Bi}}$ of $\boldsymbol{U_B}$: $\boldsymbol{U_{Bi}} \subset \boldsymbol{U_B}$

   For each $\boldsymbol{U_{Bi}}$, if $(\boldsymbol{U_L} \cup \boldsymbol{U_{Bi}})^{+} = \boldsymbol{U}$ under F, then $\boldsymbol{K_i} = (\boldsymbol{U_L} \cup \boldsymbol{U_{Bi}})$ is a candidate key of R **(*)**

(*) *If* $\boldsymbol{K_i} = (\boldsymbol{U_L} \cup \boldsymbol{U_{Bi}})$ *is a candidate key of R, then we need not to check* $\boldsymbol{U_{Bj}} \subset \boldsymbol{U_B}$ *where* $\boldsymbol{U_{Bi}} \subset \boldsymbol{U_{Bj}}$

Key-finding algorithm (2)

By Hossein Saiedian and Thomas Spencer

- A simple categorization of attributes into the sets U_L, U_L and U_L allows to distinguish between those attributes that will participate in the candidate keys of a relational database schema and those that do not.
- The algorithm (2) finds all candidate keys.

Q & A

Exercise 1

Consider the universal relation R = {*A, B, C, D, E, F*} and the set of functional dependencies:

1) $A \rightarrow B$
2) $C, D \rightarrow A$
3) $B, C \rightarrow D$
4) $A, E \rightarrow F$
5) $C, E \rightarrow D$

What is the key for *R?*

Exercise 2

Consider the universal relation R = {*A, B, C, D, E, F*} and the set of functional dependencies:

1) $A, D \rightarrow B$
2) $A, B \rightarrow E$
3) $C \rightarrow D$
4) $B \rightarrow C$
5) $A, C \rightarrow F$

What is the key for *R?* Decompose *R* into 2NF, 3NF, and BCNF relations.

Exercise 3

Consider the universal relation R = {*A, B, C, D, E, F*} and the set of functional dependencies:

1) *A* → B
2) *C* → A, *D*
3) *A, F* → C, *E*

What is the key for *R?* Decompose *R* into 2NF, 3NF, and BCNF relations.

Exercise 4

Consider the universal relation R = {*A, B, C, D, E, F, G, H, I, J*} and the set of functional dependencies:

1) *A, B* → *C*
2) *B, D* → *E, F*
3) *A, D* → *G, H*
4) *A* → *I*
5) *H* → *J*

What is the key for *R?* Decompose *R* into 2NF, 3NF, and BCNF relations.

Review questions

1) Define first, second, and third normal forms when only primary keys are considered. How do the general definitions of 2NF and 3NF, which consider all keys of a relation, differ from those that consider only primary keys?
2) Define Boyce-Codd normal form. How does it differ from 3NF? Why is it considered a stronger form of 3NF?
3) What is a minimal set of functional dependencies? Does every set of dependencies have a minimal equivalent set? Is it always unique?
